

**AMENDMENT TO H.R. 910, AS REPORTED
OFFERED BY MR. CONNOLLY OF VIRGINIA**

Redesignate sections 2 through 4 as sections 3 through 5, respectively, and insert after section 1 the following:

1 SEC. 2. FINDINGS.

2 The Congress finds as follows:

3 (1) Warming of the climate system is unequivocal, as is now evident from observations of increases
4 in global average air and ocean temperatures, widespread melting of snow and ice and rising global average
5 sea level.
6
7

8 (2) Eleven of the last twelve years (1995–2006)
9 rank among the twelve warmest years in the instrumental record of global surface temperature (since
10 1850). The 100-year linear trend (1906–2005) of
11 0.74 [0.56 to 0.92]°C is larger than the corresponding trend of 0.6 [0.4 to 0.8]°C (1901–2000)
12 given in the Third Assessment Report (TAR). The
13 temperature increase is widespread over the globe
14 and is greater at higher northern latitudes. Land regions
15 have warmed faster than the oceans.
16
17

1 (3) Rising sea level is consistent with warming.
2 Global average sea level has risen since 1961 at an
3 average rate of 1.8 [1.3 to 2.3] mm/yr and since
4 1993 at 3.1 [2.4 to 3.8] mm/yr, with contributions
5 from thermal expansion, melting glaciers and ice
6 caps, and the polar ice sheets. Whether the faster
7 rate for 1993 to 2003 reflects decadal variation or
8 an increase in the longer-term trend is unclear.

9 (4) Observed decreases in snow and ice extent
10 are also consistent with warming. Satellite data
11 since 1978 show that annual average Arctic sea ice
12 extent has shrunk by 2.7 [2.1 to 3.3] percent per
13 decade, with larger decreases in summer of 7.4 [5.0
14 to 9.8] percent per decade. Mountain glaciers and
15 snow cover on average have declined in both hemi-
16 spheres.

17 (5) From 1900 to 2005, precipitation increased
18 significantly in eastern parts of North and South
19 America, northern Europe and northern and central
20 Asia but declined in the Sahel, the Mediterranean,
21 southern Africa and parts of southern Asia. Glob-
22 ally, the area affected by drought has likely in-
23 creased since the 1970s.

24 (6) It is very likely that over the past 50 years:
25 cold days, cold nights and frosts have become less

1 frequent over most land areas, and hot days and hot
2 nights have become more frequent. It is likely that:
3 heat waves have become more frequent over most
4 land areas, the frequency of heavy precipitation
5 events has increased over most areas, and since
6 1975 the incidence of extreme high sea level has in-
7 creased worldwide.

8 (7) There is observational evidence of an in-
9 crease in intense tropical cyclone activity in the
10 North Atlantic since about 1970, with limited evi-
11 dence of increases elsewhere. There is no clear trend
12 in the annual numbers of tropical cyclones. It is dif-
13 ficult to ascertain longer-term trends in cyclone ac-
14 tivity, particularly prior to 1970.

15 (8) Average Northern Hemisphere temperatures
16 during the second half of the 20th century were very
17 likely higher than during any other 50-year period in
18 the last 500 years and likely the highest in at least
19 the past 1300 years.

20 (9) Observational evidence from all continents
21 and most oceans shows that many natural systems
22 are being affected by regional climate changes, par-
23 ticularly temperature increases.

24 (10) Changes in snow, ice and frozen ground
25 have with high confidence increased the number and

1 size of glacial lakes, increased ground instability in
2 mountain and other permafrost regions and led to
3 changes in some Arctic and Antarctic ecosystems.

4 (11) There is high confidence that some
5 hydrological systems have also been affected through
6 increased runoff and earlier spring peak discharge in
7 many glacier- and snow-fed rivers and through ef-
8 fects on thermal structure and water quality of
9 warming rivers and lakes.

10 (12) In terrestrial ecosystems, earlier timing of
11 spring events and pole ward and upward shifts in
12 plant and animal ranges are with very high con-
13 fidence linked to recent warming. In some marine
14 and freshwater systems, shifts in ranges and
15 changes in algal, plankton, and fish abundance are
16 with high confidence associated with rising water
17 temperatures, as well as related changes in ice cover,
18 salinity, oxygen levels, and circulation.

19 (13) Of the more than 29,000 observational
20 data series, from 75 studies, that show significant
21 change in many physical and biological systems,
22 more than 89 percent are consistent with the direc-
23 tion of change expected as a response to warming.
24 However, there is a notable lack of geographic bal-

1 ance in data and literature on observed changes,
2 with marked scarcity in developing countries.

3 (14) There is medium confidence that other ef-
4 fects of regional climate change on natural and
5 human environments are emerging, although many
6 are difficult to discern due to adaptation and non-
7 climatic drivers. They include effects of temperature
8 increases on agricultural and forestry management
9 at Northern Hemisphere higher latitudes, such as
10 earlier spring planting of crops, and alterations in
11 disturbance regimes of forests due to fires and pests
12 some aspects of human health, such as heat-related
13 mortality in Europe, changes in infectious disease
14 vectors in some areas, and allergenic pollen in
15 Northern Hemisphere high and mid-latitudes some
16 human activities in the Arctic (e.g. hunting and
17 travel over snow and ice) and in lower-elevation al-
18 pine areas (such as mountain sports).

19 (15) Changes in atmospheric concentrations of
20 greenhouse gases (GHGs) and aerosols, land cover
21 and solar radiation alter the energy balance of the
22 climate system.

23 (16) Global GHG emissions due to human ac-
24 tivities have grown since pre-industrial times, with
25 an increase of 70 percent between 1970 and 2004.

1 (17) Carbon dioxide (CO₂) is the most impor-
2 tant anthropogenic GHG. Its annual emissions grew
3 by about 80 percent between 1970 and 2004. The
4 long-term trend of declining CO₂ emissions per unit
5 of energy supplied reversed after 2000.

6 (18) Global atmospheric concentrations of CO₂,
7 methane (CH₄) and nitrous oxide (N₂O) have in-
8 creased markedly as a result of human activities
9 since 1750 and now far exceed pre-industrial values
10 determined from ice cores spanning many thousands
11 of years.

12 (19) Atmospheric concentrations of CO₂
13 (379ppm) and CH₄ (1774ppb) in 2005 exceed by far
14 the natural range over the last 650,000 years. Glob-
15 al increases in CO₂ concentrations are due primarily
16 to fossil fuel use, with land-use change providing an-
17 other significant but smaller contribution. It is very
18 likely that the observed increase in CH₄ concentra-
19 tion is predominantly due to agriculture and fossil
20 fuel use. CH₄ growth rates have declined since the
21 early 1990s, consistent with total emissions (sum of
22 anthropogenic and natural sources) being nearly
23 constant during this period. The increase in N₂O
24 concentration is primarily due to agriculture.

1 (20) There is very high confidence that the net
2 effect of human activities since 1750 has been one
3 of warming.

4 (21) Most of the observed increase in global av-
5 erage temperatures since the mid-20th century is
6 very likely due to the observed increase in anthropo-
7 genic GHG concentrations. It is likely that there has
8 been significant anthropogenic warming over the
9 past 50 years averaged over each continent (except
10 Antarctica).

11 (22) During the past 50 years, the sum of solar
12 and volcanic forcings would likely have produced
13 cooling. Observed patterns of warming and their
14 changes are simulated only by models that include
15 anthropogenic forcings. Difficulties remain in simu-
16 lating and attributing observed temperature changes
17 at smaller than continental scales.

18 (23) Advances since the TAR show that dis-
19 cernible human influences extend beyond average
20 temperature to other aspects of climate.

21 (24) Human influences have very likely contrib-
22 uted to sea level rise during the latter half of the
23 20th century likely contributed to changes in wind
24 patterns, affecting extra-tropical storm tracks and
25 temperature patterns likely increased temperatures

1 of extreme hot nights, cold nights and cold days
2 more likely than not increased risk of heat waves,
3 area affected by drought since the 1970s and fre-
4 quency of heavy precipitation events.

5 (25) Anthropogenic warming over the last three
6 decades has likely had a discernible influence at the
7 global scale on observed changes in many physical
8 and biological systems.

9 (26) Spatial agreement between regions of sig-
10 nificant warming across the globe and locations of
11 significant observed changes in many systems con-
12 sistent with warming is very unlikely to be due solely
13 to natural variability. Several modeling studies have
14 linked some specific responses in physical and bio-
15 logical systems to anthropogenic warming.

16 (27) More complete attribution of observed nat-
17 ural system responses to anthropogenic warming is
18 currently prevented by the short time scales of many
19 impact studies, greater natural climate variability at
20 regional scales, contributions of non-climate factors,
21 and limited spatial coverage of studies.

22 (28) There is high agreement and much evi-
23 dence that with current climate change mitigation
24 policies and related sustainable development prac-

1 tices, global GHG emissions will continue to grow
2 over the next few decades.

3 (29) The IPCC Special Report on Emissions
4 Scenarios projects an increase of global GHG emis-
5 sions by 25 to 90 percent between 2000 and 2030,
6 with fossil fuels maintaining their dominant position
7 in the global energy mix to 2030 and beyond. More
8 recent scenarios without additional emissions mitiga-
9 tion are comparable in range.

10 (30) Continued GHG emissions at or above cur-
11 rent rates would cause further warming and induce
12 many changes in the global climate system during
13 the 21st century that would very likely be larger
14 than those observed during the 20th century

15 (31) For the next two decades a warming of
16 about 0.2°C per decade is projected for a range of
17 SRES emissions scenarios. Even if the concentra-
18 tions of all GHGs and aerosols had been kept con-
19 stant at year 2000 levels, a further warming of
20 about 0.1°C per decade would be expected. After-
21 wards, temperature projections increasingly depend
22 on specific emissions scenarios.

23 (32) The range of projections is broadly con-
24 sistent with the TAR, but uncertainties and upper
25 ranges for temperature are larger mainly because

1 the broader range of available models suggests
2 stronger climate-carbon cycle feedbacks. Warming
3 reduces terrestrial and ocean uptake of atmospheric
4 CO₂, increasing the fraction of anthropogenic emis-
5 sions remaining in the atmosphere. The strength of
6 this feedback effect varies markedly among models.

7 (33) Because understanding of some important
8 effects driving sea level rise is too limited, this re-
9 port does not assess the likelihood, nor provide a
10 best estimate or an upper bound for sea level rise.
11 The projections do not include uncertainties in cli-
12 mate-carbon cycle feedbacks nor the full effects of
13 changes in ice sheet flow, therefore the upper values
14 of the ranges are not to be considered upper bounds
15 for sea level rise. They include a contribution from
16 increased Greenland and Antarctic ice flow at the
17 rates observed for 1993–2003, but this could in-
18 crease or decrease in the future.

19 (34) There is now higher confidence than in the
20 TAR in projected patterns of warming and other re-
21 gional-scale features, including changes in wind pat-
22 terns, precipitation and some aspects of extremes
23 and sea ice.

24 (35) Warming greatest over land and at most
25 high northern latitudes and least over Southern

1 Ocean and parts of the North Atlantic Ocean, con-
2 tinuing recent observed trends contraction of snow
3 cover area, increases in thaw depth over most per-
4 mafrost regions and decrease in sea ice extent; in
5 some projections using SRES scenarios, Arctic late-
6 summer sea ice disappears almost entirely by the
7 latter part of the 21st century very likely increase in
8 frequency of hot extremes, heat waves and heavy
9 precipitation likely increase in tropical cyclone inten-
10 sity; less confidence in global decrease of tropical cy-
11 clone numbers pole ward shift of extra-tropical
12 storm tracks with consequent changes in wind, pre-
13 cipitation and temperature patterns very likely pre-
14 cipitation increases in high latitudes and likely de-
15 creases in most subtropical land regions, continuing
16 observed recent trends.

17 (36) There is high confidence that by mid-cen-
18 tury, annual river runoff and water availability are
19 projected to increase at high latitudes (and in some
20 tropical wet areas) and decrease in some dry regions
21 in the mid-latitudes and tropics. There is also high
22 confidence that many semi-arid areas (e.g. Medi-
23 terranean Basin, western United States, southern
24 Africa and north-eastern Brazil) will suffer a de-
25 crease in water resources due to climate change.

1 (37) Studies since the TAR have enabled more
2 systematic understanding of the timing and mag-
3 nitude of impacts related to differing amounts and
4 rates of climate change.

5 (38) AFRICA.—By 2020, between 75 and 250
6 million of people are projected to be exposed to in-
7 creased water stress due to climate change. By
8 2020, in some countries, yields from rain-fed agri-
9 culture could be reduced by up to 50 percent. Agri-
10 cultural production, including access to food, in
11 many African countries is projected to be severely
12 compromised. This would further adversely affect
13 food security and exacerbate malnutrition. Towards
14 the end of the 21st century, projected sea level rise
15 will affect low-lying coastal areas with large popu-
16 lations. The cost of adaptation could amount to at
17 least 5 to 10 percent of Gross Domestic Product
18 (GDP). By 2080, an increase of 5 to 8 percent of
19 arid and semi-arid land in Africa is projected under
20 a range of climate.

21 (39) ASIA.—By the 2050s, freshwater avail-
22 ability in Central, South, East and South-East Asia,
23 particularly in large river basins, is projected to de-
24 crease. Coastal areas, especially heavily populated
25 megadelta regions in South, East and South-East

1 Asia, will be at greatest risk due to increased flood-
2 ing from the sea and, in some megadeltas, flooding
3 from the rivers. Climate change is projected to com-
4 pound the pressures on natural resources and the
5 environment associated with rapid urbanization, in-
6 dustrialization and economic development. Endemic
7 morbidity and mortality due to diarrhoeal disease
8 primarily associated with floods and droughts are
9 expected to rise in East, South and South-East Asia
10 due to projected changes in the hydrological cycle.

11 (40) AUSTRALIA AND NEW ZEALAND.—By
12 2020, significant loss of biodiversity is projected to
13 occur in some ecologically rich sites, including the
14 Great Barrier Reef and Queensland Wet Tropics.

15 (41) By 2030, water security problems are pro-
16 jected to intensify in southern and eastern Australia
17 and, in New Zealand, in Northland and some east-
18 ern regions.

19 (42) By 2030, production from agriculture and
20 forestry is projected to decline over much of south-
21 ern and eastern Australia, and over parts of eastern
22 New Zealand, due to increased drought and fire.
23 However, in New Zealand, initial benefits are pro-
24 jected in some other regions.

1 (43) By 2050, ongoing coastal development and
2 population growth in some areas of Australia and
3 New Zealand are projected to exacerbate risks from
4 sea level rise and increases in the severity and fre-
5 quency of storms and coastal flooding.

6 (44) EUROPE.—Climate change is expected to
7 magnify regional differences in Europe’s natural re-
8 sources and assets. Negative impacts will include in-
9 creased risk of inland flash floods and more frequent
10 coastal flooding and increased erosion (due to storm-
11 iness and sea level rise). Mountainous areas will face
12 glacier retreat, reduced snow cover and winter tour-
13 ism, and extensive species losses (in some areas up
14 to 60 percent under high emissions scenarios by
15 2080). In southern Europe, climate change is pro-
16 jected to worsen conditions (high temperatures and
17 drought) in a region already vulnerable to climate
18 variability, and to reduce water availability, hydro-
19 power potential, summer tourism and, in general,
20 crop productivity. Climate change is also projected
21 to increase the health risks due to heat waves and
22 the frequency of wildfires.

23 (45) LATIN AMERICA.—By mid-century, in-
24 creases in temperature and associated decreases in
25 soil water are projected to lead to gradual replace-

1 ment of tropical forest by savanna in eastern
2 Amazonia. Semi-arid vegetation will tend to be re-
3 placed by arid-land vegetation. There is a risk of sig-
4 nificant biodiversity loss through species extinction
5 in many areas of tropical Latin America. Produc-
6 tivity of some important crops is projected to de-
7 crease and livestock productivity to decline, with ad-
8 verse consequences for food security. In temperate
9 zones, soybean yields are projected to increase. Over-
10 all, the number of people at risk of hunger is pro-
11 jected to increase (TS; medium confidence). Changes
12 in precipitation patterns and the disappearance of
13 glaciers are projected to significantly affect water
14 availability for human consumption, agriculture and
15 energy generation.

16 (46) NORTH AMERICA.—Warming in western
17 mountains is projected to cause decreased snowpack,
18 more winter flooding and reduced summer flows, ex-
19 acerbating competition for over-allocated water re-
20 sources. In the early decades of the century, mod-
21 erate climate change is projected to increase aggre-
22 gate yields of rain-fed agriculture by 5 to 20 per-
23 cent, but with important variability among regions.
24 Major challenges are projected for crops that are
25 near the warm end of their suitable range or which

1 depend on highly utilized water resources. Cities
2 that currently experience heat waves are expected to
3 be further challenged by an increased number, inten-
4 sity and duration of heat waves during the course of
5 the century, with potential for adverse health im-
6 pacts. Coastal communities and habitats will be in-
7 creasingly stressed by climate change impacts inter-
8 acting with development and pollution.

9 (47) POLAR REGIONS.—The main projected bio-
10 physical effects are reductions in thickness and ex-
11 tent of glaciers, ice sheets and sea ice, and changes
12 in natural ecosystems with detrimental effects on
13 many organisms including migratory birds, mam-
14 mals and higher predators. For human communities
15 in the Arctic, impacts, particularly those resulting
16 from changing snow and ice conditions, are pro-
17 jected to be mixed. Detrimental impacts would in-
18 clude those on infrastructure and traditional indige-
19 nous ways of life. In both Polar Regions, specific
20 ecosystems and habitats are projected to be vulner-
21 able, as climatic barriers to species invasions are
22 lowered.

23 (48) SMALL ISLANDS.—Sea level rise is ex-
24 pected to exacerbate inundation, storm surge, ero-
25 sion and other coastal hazards, thus threatening

1 vital infrastructure, settlements and facilities that
2 support the livelihood of island communities. Dete-
3 rioration in coastal conditions, for example through
4 erosion of beaches and coral bleaching, is expected
5 to affect local resources. By mid-century, climate
6 change is expected to reduce water resources in
7 many small islands, e.g. in the Caribbean and Pa-
8 cific, to the point where they become insufficient to
9 meet demand during low-rainfall periods. With high-
10 er temperatures, increased invasion by non-native
11 species is expected to occur, particularly on mid- and
12 high-latitude islands.

13 (49) Some systems, sectors and regions are
14 likely to be especially affected by climate change.

15 (50) SYSTEMS AND SECTORS/PARTICULAR ECO-
16 SYSTEMS; TERRESTRIAL.—Tundra, boreal forest and
17 mountain regions because of sensitivity to warming;
18 Mediterranean-type ecosystems because of reduction
19 in rainfall; and tropical rainforests where precipita-
20 tion declines coastal: mangroves and salt marshes,
21 due to multiple stresses marine: coral reefs due to
22 multiple stresses; the sea ice biome because of sensi-
23 tivity to warming water resources in some dry re-
24 gions at mid-latitudes and in the dry tropics, due to
25 changes in rainfall and evapotranspiration, and in

1 areas dependent on snow and ice melt agriculture in
2 low latitudes, due to reduced water availability low-
3 lying coastal systems, due to threat of sea level rise
4 and increased risk from extreme weather events
5 human health in populations with low adaptive ca-
6 pacity.

7 (51) REGIONS.—The Arctic, because of the im-
8 pacts of high rates of projected warming on natural
9 systems and human communities Africa, because of
10 low adaptive capacity and projected climate change
11 impacts small islands, where there is high exposure
12 of population and infrastructure to projected climate
13 change impacts Asian and African megadeltas, due
14 to large populations and high exposure to sea level
15 rise, storm surges and river flooding.

16 (52) Within other areas, even those with high
17 incomes, some people (such as the poor, young chil-
18 dren and the elderly) can be particularly at risk, and
19 also some areas and some activities.

20 (53) OCEAN ACIDIFICATION.—The uptake of
21 anthropogenic carbon since 1750 has led to the
22 ocean becoming more acidic with an average de-
23 crease in pH of 0.1 units. Increasing atmospheric
24 CO₂ concentrations lead to further acidification.
25 Projections based on SRES scenarios give a reduc-

1 tion in average global surface ocean pH of between
2 0.14 and 0.35 units over the 21st century. While the
3 effects of observed ocean acidification on the marine
4 biosphere are as yet undocumented, the progressive
5 acidification of oceans is expected to have negative
6 impacts on marine shell-forming organisms (e.g. corals)
7 and their dependent species.

8 (54) Altered frequencies and intensities of extreme
9 weather, together with sea level rise, are expected to
10 have mostly adverse effects on natural and
11 human systems.

12 (55) Over most land areas, warmer and fewer
13 cold days and nights, warmer and more frequent hot
14 days and nights; Increased yields in colder environments;
15 decreased yields in warmer environments; increased
16 insect outbreaks; effects on water resources relying on
17 snowmelt; effects on some water supplies; reduced human
18 mortality from decreased cold exposure; reduced energy
19 demand for heating; increased demand for cooling; declining
20 air quality in cities; reduced disruption to transport due
21 to snow, ice; and effects on winter tourism.

22 (56) WARM SPELLS/HEAT WAVES.—Frequency
23 increases over most land areas; Very likely Reduced
24 yields in warmer regions due to heat stress; in-

1 creased danger of wildfire; Increased water demand;
2 water quality problems, e.g. algal blooms; Increased
3 risk of heat-related mortality, especially for the el-
4 derly, chronically sick, very young and socially iso-
5 lated; Reduction in quality of life for people in warm
6 areas without appropriate housing; impacts on the
7 elderly, very young and poor.

8 (57) Frequency of heavy precipitation events
9 will increase over most areas. Very likely damage to
10 crops; soil erosion, inability to cultivate land due to
11 water logging of soils.

12 (58) Adverse effects on quality of surface and
13 groundwater; contamination of water supply; water
14 scarcity may be relieved. Increased risk of deaths,
15 injuries and infectious, respiratory and skin diseases.
16 Disruption of settlements, commerce, transport and
17 societies due to flooding; pressures on urban and
18 rural infrastructures; loss of property.

19 (59) Area affected by drought increases the
20 likelihood of land degradation; lower yields/crop
21 damage and failure; increased livestock deaths; in-
22 creased risk of wildfire; more widespread water
23 stress; increased risk of food and water shortage; in-
24 creased risk of malnutrition; increased risk of water-
25 and food- borne diseases; water shortage for settle-

1 ments, industry and societies; reduced hydropower
2 generation potentials; potential for population migra-
3 tion.

4 (60) Intense tropical cyclone activity increases
5 the likelihood of damage to crops; windthrow (up-
6 rooting) of trees; damage to coral reefs.

7 (61) Power outages causing disruption of public
8 water supply; increased risk of deaths, injuries,
9 water- and food- borne diseases; post-traumatic
10 stress disorders Disruption by flood and high winds;
11 withdrawal of risk coverage in vulnerable areas by
12 private insurers; potential for population migrations;
13 loss of property.

14 (62) Increased incidence of extreme high sea
15 level (excludes tsunamis).

16 (63) Salinisation of irrigation water, estuaries
17 and fresh- water systems; decreased freshwater
18 availability due to saltwater intrusion; increased risk
19 of deaths and injuries by drowning in floods; migra-
20 tion-related health effects; Costs of coastal protec-
21 tion versus costs of land-use relocation; potential for
22 movement of populations and infrastructure.

23 (64) Contraction of the Greenland ice sheet is
24 projected to continue to contribute to sea level rise
25 after 2100. Current models suggest virtually com-

1 plete elimination of the Greenland ice sheet and a
2 resulting contribution to sea level rise of about 7m
3 if global average warming were sustained for mil-
4 lennia in excess of 1.9 to 4.6°C relative to pre-indus-
5 trial values. The corresponding future temperatures
6 in Greenland are comparable to those inferred for
7 the last interglacial period 125,000 years ago, when
8 palaeoclimatic information suggests reductions of
9 polar land ice extent and 4 to 6m of sea level rise.

10 (65) Current global model studies project that
11 the Antarctic ice sheet will remain too cold for wide-
12 spread surface melting and gain mass due to in-
13 creased snowfall. However, net loss of ice mass could
14 occur if dynamical ice discharge dominates the ice
15 sheet mass balance.

16 (66) Anthropogenic warming could lead to some
17 impacts that are abrupt or irreversible, depending
18 upon the rate and magnitude of the climate change.

19 (67) Partial loss of ice sheets on polar land
20 could imply meters of sea level rise, major changes
21 in coastlines and inundation of low-lying areas, with
22 greatest effects in river deltas and low-lying islands.
23 Such changes are projected to occur over millennial
24 time scales, but more rapid sea level rise on century
25 time scales cannot be excluded.

1 (68) Climate change is likely to lead to some ir-
2 reversible impacts. There is medium confidence that
3 approximately 20 to 30 percent of species assessed
4 so far are likely to be at increased risk of extinction
5 if increases in global average warming exceed 1.5 to
6 2.5°C (relative to 1980–1999). As global average
7 temperature increase exceeds about 3.5°C, model
8 projections suggest significant extinctions (40 to 70
9 percent of species assessed) around the globe.

10 (69) Based on current model simulations, the
11 meridional overturning circulation (MOC) of the At-
12 lantic Ocean will very likely slow down during the
13 21st century; nevertheless temperatures over the At-
14 lantic and Europe are projected to increase. The
15 MOC is very unlikely to undergo a large abrupt
16 transition during the 21st century. Longer-term
17 MOC changes cannot be assessed with confidence.
18 Impacts of large-scale and persistent changes in the
19 MOC are likely to include changes in marine eco-
20 system productivity, fisheries, ocean CO₂ uptake,
21 oceanic oxygen concentrations and terrestrial vegeta-
22 tion. Changes in terrestrial and ocean CO₂ uptake
23 may feedback on the climate system.

24 (70) A wide array of adaptation options is
25 available, but more extensive adaptation than is cur-

1 rently occurring is required to reduce vulnerability to
2 climate change. There are barriers, limits and costs,
3 which are not fully understood.

4 (71) Societies have a long record of managing
5 the impacts of weather- and climate-related events.
6 Nevertheless, additional adaptation measures will be
7 required to reduce the adverse impacts of projected
8 climate change and variability, regardless of the
9 scale of mitigation undertaken over the next two to
10 three decades. Moreover, vulnerability to climate
11 change can be exacerbated by other stresses. These
12 arise from, for example, current climate hazards,
13 poverty and unequal access to resources, food inse-
14 curity, trends in economic globalization, conflict and
15 incidence of diseases such as HIV/AIDS.

16 (72) Some planned adaptation to climate
17 change is already occurring on a limited basis. Ad-
18 aptation can reduce vulnerability, especially when it
19 is embedded within broader sectoral initiatives.
20 There is high confidence that there are viable adap-
21 tation options that can be implemented in some sec-
22 tors at low cost, and/or with high benefit-cost ratios.
23 However, comprehensive estimates of global costs
24 and benefits of adaptation are limited.

1 (73) Selected examples of planned adaptation
2 by sector. Sector Adaptation option/strategy; under-
3 lying policy framework; key constraints and opportu-
4 nities to implementation; water expanded rainwater
5 harvesting; water storage and conservation tech-
6 niques; water re-use; desalination; water-use and ir-
7 rigation efficiency; National water policies and inte-
8 grated water resources management; water-related
9 hazards management; financial, human resources
10 and physical barriers; integrated water resources
11 management; synergies with other sectors.

12 (74) Agriculture adjustment of planting dates
13 and crop variety; crop relocation; improved land
14 management, e.g. erosion control and soil protection
15 through tree planting; R&D policies; institutional re-
16 form; land tenure and land reform; training; capac-
17 ity building; crop insurance; financial incentives, e.g.
18 subsidies and tax credits; technological and financial
19 constraints; access to new varieties; markets; longer
20 growing season in higher latitudes; revenues from
21 “new” products;

22 (75) Infrastructure/settlement (including coast-
23 al zones); relocation; seawalls and storm surge bar-
24 riers; dune reinforcement; land acquisition and cre-
25 ation of marshlands/wetlands as buffer against sea

1 level rise and flooding; protection of existing natural
2 barriers; standards and regulations that integrate
3 climate change considerations into design; land-use
4 policies; building codes; insurance.

5 (76) Financial and technological barriers; avail-
6 ability of relocation space; integrated policies and
7 management; synergies with sustainable development
8 goals; human health; heat-health action plans; emer-
9 gency medical services; improved climate-sensitive
10 disease surveillance and control; safe water and im-
11 proved sanitation Public health policies that recog-
12 nize climate risk; strengthened health services; re-
13 gional and international cooperation Limits to
14 human tolerance (vulnerable groups); knowledge lim-
15 itations; financial capacity; upgraded health services;
16 improved quality of life.

17 (77) TOURISM.—Diversification of tourism at-
18 tractions and revenues; shifting ski slopes to higher
19 altitudes and glaciers; artificial snow-making.

20 (78) Integrated planning (e.g. carrying capac-
21 ity; linkages with other sectors); financial incentives,
22 e.g. subsidies and tax credits; appeal/marketing of
23 new attractions; financial and logistical challenges;
24 potential adverse impact on other sectors (e.g. artifi-
25 cial snow-making may increase energy use); revenues

1 from “new” attractions; involvement of wider group
2 of stakeholders.

3 (79) TRANSPORTATION.—Realignment/reloca-
4 tion; design standards and planning for roads, rail
5 and other infrastructure to cope with warming and
6 drainage; integrating climate change considerations
7 into national transport policy; investment in R&D
8 for special situations; financial and technological
9 barriers; availability of less vulnerable routes; im-
10 proved technologies and integration with key sectors
11 (e.g. energy).

12 (80) ENERGY.—Strengthening of overhead
13 transmission and distribution infrastructure; under-
14 ground cabling for utilities; energy efficiency; use of
15 renewable sources; reduced dependence on single
16 sources of energy National energy policies, regula-
17 tions, and fiscal and financial incentives to encour-
18 age use of alternative sources; incorporating climate
19 change in design standards; access to viable alter-
20 natives; financial and technological barriers; accept-
21 ance of new technologies; stimulation of new tech-
22 nologies; use of local resources. (Note: Other exam-
23 ples from many sectors would include early warning
24 systems. Adaptive capacity is intimately connected to

1 social and economic development but is unevenly dis-
2 tributed across and within societies.).

3 (81) A range of barriers limits both the imple-
4 mentation and effectiveness of adaptation measures.
5 The capacity to adapt is dynamic and is influenced
6 by a society's productive base, including natural and
7 man-made capital assets, social networks and entitle-
8 ments, human capital and institutions, governance,
9 national income, health and technology. Even soci-
10 eties with high adaptive capacity remain vulnerable
11 to climate change, variability and extremes.

12 (82) Both bottom-up and top-down studies indi-
13 cate that there is high agreement and much evidence
14 of substantial economic potential for the mitigation
15 of global GHG emissions over the coming decades
16 that could offset the projected growth of global emis-
17 sions or reduce emissions below current levels. While
18 top-down and bottom-up studies are in line at the
19 global level there are considerable differences at the
20 sectoral level.

21 (83) No single technology can provide all of the
22 mitigation potential in any sector. The economic
23 mitigation potential, which is generally greater than
24 the market mitigation potential, can only be

1 achieved when adequate policies are in place and
2 barriers removed.

3 (84) Bottom-up studies suggest that mitigation
4 opportunities with net negative costs have the poten-
5 tial to reduce emissions by around 6 GtCO₂-eq/yr in
6 2030, realizing which requires dealing with imple-
7 mentation barriers.

8 (85) Future energy infrastructure investment
9 decisions, expected to exceed \$20,000,000,000,000
10 between 2005 and 2030, will have long-term impacts
11 on GHG emissions, because of the long lifetimes of
12 energy plants and other infrastructure capital stock.
13 The widespread diffusion of low-carbon technologies
14 may take many decades, even if early investments in
15 these technologies are made attractive. Initial esti-
16 mates show that returning global energy-related CO₂
17 emissions to 2005 levels by 2030 would require a
18 large shift in investment patterns, although the net
19 additional investment required ranges from neg-
20 ligible to 5 to 10 percent.

21 (86) A wide variety of policies and instruments
22 are available to governments to create the incentives
23 for mitigation action. Their applicability depends on
24 national circumstances and sectoral context.

1 (87) They include integrating climate policies in
2 wider development policies, regulations and stand-
3 ards, taxes and charges, tradable permits, financial
4 incentives, voluntary agreements, information instru-
5 ments, and research, development and demonstra-
6 tion (RD&D).

7 (88) An effective carbon-price signal could real-
8 ize significant mitigation potential in all sectors.
9 Modeling studies show that global carbon prices ris-
10 ing to \$20-80/tCO₂-eq by 2030 are consistent with
11 stabilization at around 550ppm CO₂-eq by 2100.
12 For the same stabilization level, induced techno-
13 logical change may lower these price ranges to \$5-
14 65/tCO₂-eq in 2030.

15 (89) There is high agreement and much evi-
16 dence that mitigation actions can result in near-term
17 co-benefits (e.g. improved health due to reduced air
18 pollution) that may offset a substantial fraction of
19 mitigation costs.

20 (90) There is high agreement and medium evi-
21 dence that Annex I countries' actions may affect the
22 global economy and global emissions, although the
23 scale of carbon leakage remains uncertain.

24 (91) Fossil fuel exporting nations (in both
25 Annex I and non-Annex I countries) may expect, as

1 indicated in the TAR, lower demand and prices and
2 lower GDP growth due to mitigation policies. The
3 extent of this spillover depends strongly on assump-
4 tions related to policy decisions and oil market con-
5 ditions.

6 (92) There is also high agreement and medium
7 evidence that changes in lifestyle, behavior patterns
8 and management practices can contribute to climate
9 change mitigation across all sectors.

10 (93) Many options for reducing global GHG
11 emissions through international cooperation exist.
12 There is high agreement and much evidence that no-
13 table achievements of the UNFCCC and its Kyoto
14 Protocol are the establishment of a global response
15 to climate change, stimulation of an array of na-
16 tional policies, and the creation of an international
17 carbon market and new institutional mechanisms
18 that may provide the foundation for future mitiga-
19 tion efforts. Progress has also been made in address-
20 ing adaptation within the UNFCCC and additional
21 international initiatives have been suggested.

22 (94) Greater cooperative efforts and expansion
23 of market mechanisms will help to reduce global
24 costs for achieving a given level of mitigation, or will
25 improve environmental effectiveness. Efforts can in-

1 clude diverse elements such as emissions targets;
2 sectoral, local, sub-national and regional actions;
3 RD&D programs; adopting common policies; imple-
4 menting development-oriented actions; or expanding
5 financing instruments.

6 (95) In several sectors, climate response options
7 can be implemented to realize synergies and avoid
8 conflicts with other dimensions of sustainable devel-
9 opment. Decisions about macroeconomic and other
10 non-climate policies can significantly affect emis-
11 sions, adaptive capacity and vulnerability.

12 (96) Making development more sustainable can
13 enhance mitigative and adaptive capacities, reduce
14 emissions and reduce vulnerability, but there may be
15 barriers to implementation. On the other hand, it is
16 very likely that climate change can slow the pace of
17 progress towards sustainable development. Over the
18 next half-century, climate change could impede
19 achievement of the Millennium Development Goals.

20 (97) Determining what constitutes “dangerous
21 anthropogenic interference with the climate system”
22 in relation to Article 2 of the UNFCCC involves
23 value judgments. Science can support informed deci-
24 sions on this issue, including by providing criteria

1 for judging which vulnerabilities might be labeled
2 “key”.

3 (98) Key vulnerabilities may be associated with
4 many climate-sensitive systems, including food sup-
5 ply, infrastructure, health, water resources, coastal
6 systems, ecosystems, global biogeochemical cycles,
7 ice sheets and modes of oceanic and atmospheric cir-
8 culation.

9 (99) The five “reasons for concern” identified
10 in the TAR remain a viable framework to consider
11 key vulnerabilities. These “reasons” are assessed
12 here to be stronger than in the TAR. Many risks are
13 identified with higher confidence. Some risks are
14 projected to be larger or to occur at lower increases
15 in temperature. Understanding about the relation-
16 ship between impacts (the basis for “reasons for
17 concern” in the TAR) and vulnerability (that in-
18 cludes the ability to adapt to impacts) has improved.
19 This is due to more precise identification of the cir-
20 cumstances that make systems, sectors and regions
21 especially vulnerable and growing evidence of the
22 risks of very large impacts on multiple-century time
23 scales.

24 (100) RISKS TO UNIQUE AND THREATENED
25 SYSTEMS.—There is new and stronger evidence of

1 observed impacts of climate change on unique and
2 vulnerable systems (such as polar and high moun-
3 tain communities and ecosystems), with increasing
4 levels of adverse impacts as temperatures increase
5 further. An increasing risk of species extinction and
6 coral reef damage is projected with higher con-
7 fidence than in the TAR as warming proceeds.
8 There is medium confidence that approximately 20
9 to 30 percent of plant and animal species assessed
10 so far are likely to be at increased risk of extinction
11 if increases in global average temperature exceed 1.5
12 to 2.5°C over 1980–1999 levels. Confidence has in-
13 creased that a 1 to 2°C increase in global mean tem-
14 perature above 1990 levels (about 1.5 to 2.5°C
15 above pre-industrial) poses significant risks to many
16 unique and threatened systems including many bio-
17 diversity hotspots. Corals are vulnerable to thermal
18 stress and have low adaptive capacity. Increases in
19 sea surface temperature of about 1 to 3°C are pro-
20 jected to result in more frequent coral bleaching
21 events and widespread mortality, unless there is
22 thermal adaptation or acclimatization by corals. In-
23 creasing vulnerability of indigenous communities in
24 the Arctic and small island communities to warming
25 is projected.

1 (101) RISKS OF EXTREME WEATHER
2 EVENTS.—Responses to some recent extreme events
3 reveal higher levels of vulnerability than the TAR.
4 There is now higher confidence in the projected in-
5 creases in droughts, heat waves and floods, as well
6 as their adverse impacts.

7 (102) DISTRIBUTION OF IMPACTS AND
8 VULNERABILITIES.—There are sharp differences
9 across regions and those in the weakest economic
10 position are often the most vulnerable to climate
11 change. There is increasing evidence of greater vul-
12 nerability of specific groups such as the poor and el-
13 derly not only in developing but also in developed
14 countries. Moreover, there is increased evidence that
15 low-latitude and less developed areas generally face
16 greater risk, for example in dry areas and
17 megadeltas.

18 (103) AGGREGATE IMPACTS.—Compared to the
19 TAR, initial net market-based benefits from climate
20 change are projected to peak at a lower magnitude
21 of warming, while damages would be higher for larg-
22 er magnitudes of warming. The net costs of impacts
23 of increased warming are projected to increase over
24 time.

1 (104) RISKS OF LARGE-SCALE
2 SINGULARITIES.—There is high confidence that glob-
3 al warming over many centuries would lead to a sea
4 level rise contribution from thermal expansion alone
5 that is projected to be much larger than observed
6 over the 20th century, with loss of coastal area and
7 associated impacts. There is better understanding
8 than in the TAR that the risk of additional contribu-
9 tions to sea level rise from both the Greenland and
10 possibly Antarctic ice sheets may be larger than pro-
11 jected by ice sheet models and could occur on cen-
12 tury time scales. This is because ice dynamical proc-
13 esses seen in recent observations but not fully in-
14 cluded in ice sheet models assessed in the AR4 could
15 increase the rate of ice loss.

16 (105) There is high confidence that neither ad-
17 aptation nor mitigation alone can avoid all climate
18 change impacts; however, they can complement each
19 other and together can significantly reduce the risks
20 of climate change.

21 (106) Adaptation is necessary in the short and
22 longer term to address impacts resulting from the
23 warming that would occur even for the lowest sta-
24 bilization scenarios assessed. There are barriers, lim-
25 its and costs, but these are not fully understood.

1 Unmitigated climate change would, in the long term,
2 be likely to exceed the capacity of natural, managed
3 and human systems to adapt. The time at which
4 such limits could be reached will vary between sec-
5 tors and regions. Early mitigation actions would
6 avoid further locking in carbon intensive infrastruc-
7 ture and reduce climate change and associated adap-
8 tation needs.

9 (107) Many impacts can be reduced, delayed or
10 avoided by mitigation. Mitigation efforts and invest-
11 ments over the next two to three decades will have
12 a large impact on opportunities to achieve lower sta-
13 bilization levels. Delayed emission reductions signifi-
14 cantly constrain the opportunities to achieve lower
15 stabilization levels and increase the risk of more se-
16 vere climate change impacts.

17 (108) In order to stabilize the concentration of
18 GHGs in the atmosphere, emissions would need to
19 peak and decline thereafter. The lower the stabiliza-
20 tion level, the more quickly this peak and decline
21 would need to occur.

22 (109) Sea level rise under warming is inevi-
23 table. Thermal expansion would continue for many
24 centuries after GHG concentrations have stabilized,
25 for any of the stabilization levels assessed, causing

1 an eventual sea level rise much larger than projected
2 for the 21st century. The eventual contributions
3 from Greenland ice sheet loss could be several me-
4 ters, and larger than from thermal expansion, should
5 warming in excess of 1.9 to 4.6°C above pre-indus-
6 trial be sustained over many centuries. The long
7 time scales of thermal expansion and ice sheet re-
8 sponse to warming imply that stabilization of GHG
9 concentrations at or above present levels would not
10 stabilize sea level for many centuries.

11 (110) There is high agreement and much evi-
12 dence that all stabilization levels assessed can be
13 achieved by deployment of a portfolio of technologies
14 that are either currently available or expected to be
15 commercialized in coming decades, assuming appro-
16 priate and effective incentives are in place for their
17 development, acquisition, deployment and diffusion
18 and addressing related barriers.

19 (111) All assessed stabilization scenarios indi-
20 cate that 60 to 80 percent of the reductions would
21 come from energy supply and use and industrial
22 processes, with energy efficiency playing a key role
23 in many scenarios. Including non-CO₂ and CO₂
24 land-use and forestry mitigation options provides
25 greater flexibility and cost-effectiveness. Low sta-

1 bilization levels require early investments and sub-
2 stantially more rapid diffusion and commercializa-
3 tion of advanced low-emissions technologies.

4 (112) Without substantial investment flows and
5 effective technology transfer, it may be difficult to
6 achieve emission reduction at a significant scale. Mo-
7 bilizing financing of incremental costs of low-carbon
8 technologies is important.

9 (113) The macro-economic costs of mitigation
10 generally rise with the stringency of the stabilization
11 target. For specific countries and sectors, costs vary
12 considerably from the global average.

13 (114) In 2050, global average macro-economic
14 costs for mitigation towards stabilization between
15 710 and 445ppm CO₂-eq are between a 1 percent
16 gain and 5.5 percent decrease of global GDP. This
17 corresponds to slowing average annual global GDP
18 growth by less than 0.12 percentage points.

19 (115) Responding to climate change involves an
20 iterative risk management process that includes both
21 adaptation and mitigation and takes into account
22 climate change damages, co-benefits, sustainability,
23 equity and attitudes to risk.

24 (116) Impacts of climate change are very likely
25 to impose net annual costs, which will increase over

1 time as global temperatures increase. Peer-reviewed
2 estimates of the social cost of carbon in 2005 aver-
3 age \$12 per ton of CO₂, but the range from 100 es-
4 timates is large (-\$3 to \$95/tCO₂). This is due in
5 large part to differences in assumptions regarding
6 climate sensitivity, response lags, the treatment of
7 risk and equity, economic and non-economic impacts,
8 the inclusion of potentially catastrophic losses and
9 discount rates. Aggregate estimates of costs mask
10 significant differences in impacts across sectors, re-
11 gions and populations and very likely underestimate
12 damage costs because they cannot include many
13 non-quantifiable impacts.

14 (117) Limited and early analytical results from
15 integrated analyses of the costs and benefits of miti-
16 gation indicate that they are broadly comparable in
17 magnitude, but do not as yet permit an unambig-
18 uous determination of an emissions pathway or sta-
19 bilization level where benefits exceed costs.

20 (118) Climate sensitivity is a key uncertainty
21 for mitigation scenarios for specific temperature lev-
22 els.

23 (119) Choices about the scale and timing of
24 GHG mitigation involve balancing the economic
25 costs of more rapid emission reductions now against

- 1 the corresponding medium-term and long-term cli-
- 2 mate risks of delay.
